FOREWORD

The study reported herein constitutes a portion of the Mobility Environmental Research Study (MERS), sponsored by the Office, Secretary of Defense, Advanced Research Projects Agency (ARPA), Directorate of Remote Area Conflict, for which the U. S. Army Engineer Waterways Experiment Station (WES) is the prime contractor, and the U. S. Army Materiel Command (AMC) is the service agent. The broad mission of Project MERS is to determine the effects of the various features of physical environment on the performance of cross-country, ground-contact vehicles and to provide therefrom data which can be used to improve both the design and employment of such vehicles. One criterion of the project is that the data be interpretable in terms of vehicle requirements for Southeast Asia. Most of the funds employed for this study were allocated to WES through AMC under ARPA Order No. 400. The remaining funds were provided by the Directorate of Research and Development, AMC, as part of Department of the Army Project No. 1-V-0-21701-A-046, "Trafficability and Mobility Research," Task 1-V-0-21701-A-046-02, "Surface Mobility."

The study was performed by personnel of WES during the period August 1964-May 1966. The study was assigned to the Army Mobility Research Branch (AMRB), Mobility and Environmental (M&E) Division. Mr. M. P. Meyer had the primary responsibility for the general conduct of the study including the preparation of this report. Mr. J. G. Kennedy programmed the data for computer analysis. Mr. G. T. Ellis compiled the data and assisted in the analysis. Mr. C. A. Blackmon wrote the appendix. Others assisting in the study include Messrs. S. M. Hodge, J. E. Lee, and H. D. Molthan. All phases of the study were under the direct supervision of Mr. E. S. Rush, Chief of the Trafficability Section, AMRB, and the general supervision of

Dr. D. R. Freitag, Chief, AMRB; Mr. A. A. Rula, Chief, MERS Branch; Messrs. W. G. Shockley and S. J. Knight, Chief and Assistant Chief, respectively, M&E Division; and Mr. W. J. Turnbull, Technical Assistant for Soils and Environmental Engineering.

Directors of the WES during the conduct of this study and the preparation of this report were Col. Alex G. Sutton, Jr., CE, and Col. John R. Oswalt, Jr., CE. Technical Director was Mr. J. B. Tiffany.

SUMMARY

The study reported herein consisted of a statistical analysis of the principal factors that influence soil trafficability and the application of the analysis to the development of a scheme for classifying soils under generally wet conditions in Thailand. The scheme is essentially a listing of soil types (in terms of the Unified Soil Classification System and the U. S. Department of Agriculture textural classification system) in decreasing order of median rating cone index. Means and ranges are given for each soil type in high- and low-topography positions for average and highest soil-moisture conditions during the wet season. The probability of successful negotiation of a soil type by military vehicles can be ascertained by comparing vehicle cone indexes with the frequency distribution of rating cone indexes for the soils. Results of the studies performed in the development of the trafficability scheme are summarized as follows:

- a. The probability of "go" for a given vehicle over a given soil type is higher on high topographic positions than on low topographic positions; on low topographic positions the probability of "go" is lowest during times of maximum soil-moisture conditions. For a given topography-moisture condition the probability of "go" decreases for USCS soils in the following order: clean, coarse-grained soils, coarse-grained soils with fines, fine-grained soils, and organic soils.
- b. Soils in Thailand have slightly higher strengths under wettest soil-moisture conditions and slightly lower strengths under average soil-moisture conditions during the wet season than do soils in humid-temperate areas of the United States.

TRAFFICABILITY CLASSIFICATION OF THAILAND SOILS

PART I: INTRODUCTION

Background

1. The study reported herein is a part of an extensive investigation conducted to develop techniques and procedures for determining off-road soil conditions in Thailand and a graphic means of presenting these conditions which will show the relations between vehicle mobility, soil type and moisture content, and slope. This study consisted of a statistical analysis of the principal factors that influence soil trafficability and the application of the analysis in developing a scheme for classifying Thailand soils under generally wet conditions. The scheme presented herein is essentially the same as that reported in a previous WES publication.¹ The major differences are that this scheme is applied to a more restricted area, and some refinement of analytical procedures has been made.

Purpose

2. The purpose of this study was to develop a scheme for classifying the trafficability of Thailand soils in the wet season based on identification of the soils in terms of the Unified Soil Classification System (USCS) and the U. S. Department of Agriculture (USDA) textural classification system, general topographic data, and two general levels of soil-moisture content.

Scope

3. Trafficability data collected at 846 sites in Thailand on coarse-grained soils with fines and fine-grained soils of the 0- to 6- and 6- to 12-in. soil layers were statistically analyzed in the development of a trafficability classification scheme. In 1964 data from 238 sites were collected specifically for this study. Other data used were collected in various Mobility Environmental Research Study (MERS) programs including:

a preliminary survey of environmental factors affecting ground mobility in Thailand,² performed in 1962; the study of a quantitative method for describing terrain for ground mobility, surface composition,³ performed in 1964-1965; a study of soil moisture-strength characteristics of selected soils in Thailand,⁴ performed in 1963-1965; a study of selected airphoto patterns of terrain features,⁵ performed in 1964-1965 by the U. S. Army Cold Regions Research and Engineering Laboratory (CRREL); and tests to develop an analytical model for predicting cross-country vehicle performance,⁶ performed in 1965. Most of these data came from the Chiang Mai, Nakhon Sawan, Khon Kaen, Lop Buri, Chanthaburi, and Pran Buri study areas. Analyses were made of cone index, remolding index, rating cone index, surface shear strength, moisture content, density, and specific gravity of soils of low and high topography identified according to the USCS and the USDA textural classification system.

General Approach

4. A soil trafficability classification scheme, if it is to be practicable, must first name or identify the soils according to some recognized system of soil classification, then establish trafficability limits for each soil type, and finally, if feasible, collect the various soil types into a small number of groups, each exhibiting a discrete trafficability behavior. The ideal scheme would be one that provides for consideration and evaluation of all aspects of the environment (pedologic, geologic, hydrologic, physiographic, climatic, and vegetative) that affect the trafficability of the soil. The scheme reported herein considers the soil type under very general space and time conditions in a tropical climate. Further refinement according to the environmental characteristics mentioned previously must await the collection of additional data and further analysis.

5. Because their trafficability behavior is not materially affected by moisture content, clean sands and gravel have been given a distinct place in the soil trafficability classification scheme and have been excluded from the various statistical analyses that are presented in this report.

6. The soil trafficability classification scheme presented in this report may be considered a composite classification scheme because it uses two well-known systems of soil identification and is based on two moisture levels. The two soil classification systems used are the USCS⁷ (fig. 1) and the USDA soil textural classification system⁸ (fig. 2). The USCS employs soil texture, plasticity, and organic content to name or type soils, whereas the USDA system is based solely on grain size distribution. Because the USCS characterizes soils on the basis of their engineering behavior, it is considered to be more applicable to the development of a soil trafficability classification scheme than the USDA system. However, since many areas in Thailand and other areas in Southeast Asia are mapped in USDA terms, it was also considered desirable to develop a scheme in USDA terms.

Fig. 1. Unified Soil Classification System

Fig. 2. USDA soil textural classification system

PART II: TRAFFICABILITY FACTORS

7. Trafficability is defined as the capacity of a soil to withstand traffic by vehicles. It is an important aspect of cross-country movement which may be defined as the ability of terrain to permit the movement of vehicles. The factors that influence cross-country movement are numerous. They include not only the many variables which combine to determine the strength and other physical properties of soils, but also slope and other natural obstacles such as drainageways, scarpes, vegetation, and microrelief features, as well as man-made obstacles such as railroad embankments, canals, paddy dikes, etc. The investigation reported herein deals mainly with the trafficability of soils. However, the effects of slope are also considered.

Soil Bearing and Traction Capacities

8. Bearing and traction capacities are primarily functions of strength (or shearing resistance) of a soil. Bearing capacity is the ability of a soil to support a vehicle without undue sinkage; traction capacity is the ability of a soil to provide sufficient resistance between the propulsion element of a vehicle and the soil for the necessary thrust to move the vehicle forward. The trafficability of a soil is considered adequate for a given vehicle if the soil has sufficient bearing capacity to support the vehicle and sufficient traction capacity to enable the vehicle to develop the forward thrust necessary to overcome its rolling resistance.

Methods of Measuring and Evaluating Soil Trafficability

9. The soil strength measurements used in the WES system for predicting vehicle performance were used in developing the soil trafficability classification scheme discussed in this report. It has been demonstrated that the effect of soil on the performance of vehicles in terms of "go"*

* In this report "go" means that 50 vehicles can pass in straight-line traffic or one vehicle can execute severe maneuvers without becoming immobilized.

and "no go," slope-climbing ability, drawbar pull, and force required to tow the vehicle can be predicted with reasonable accuracy if the mass and surface soil strengths are not vastly different. If the mass soil strength is high and the surface is wet or consists of a thin, soft soil layer, the vehicle will sink very little, but forward motion may be denied because of loss of traction. Present methods for predicting the performance of vehicles on such soils are not entirely satisfactory. Previous investigations have also shown that the change in strength of a soil which will be developed under vehicular traffic differs significantly for fine-grained and coarse-grained soils; therefore, the measurement and evaluation methods differ somewhat. These differences are discussed in the following paragraphs.

Soil strength measurements used
for determining trafficability

10. Fine-grained soils and sands with fines, poorly drained. In fine-grained soils and in sands with fines, poorly drained, cone index (CI) and remolding index (RI) measurements are necessary to define soil trafficability. The CI provides an index of the *in-situ* or undisturbed shear strength of the soil prior to vehicular traffic. It, by itself, is inadequate for predicting the soil strength after repeated traffic by a vehicle because repetitive traffic invariably remolds the soil, thus altering its strength. The probable effect of vehicular traffic on soil strength is obtained from the RI, which indicates the direction and magnitude of the strength change that can be anticipated under vehicular traffic. An RI less than 1.00 denotes a strength loss as a result of remolding; an RI greater than 1.00 indicates a gain in strength. For example, a wet silt may retain only 25% of its undisturbed strength once it is subjected to repetitive vehicular traffic.

11. The trafficability of fine-grained soils and sands with fines, poorly drained, is therefore defined in terms of a value called the rating cone index (RCI), which is the product of the CI and the RI for the same soil layer. In general, the soil layer between the 6- and 12-in. depths is critical for most military vehicles operating in such soils. However, the depth of the critical layer varies with the strength profile of the soil and the vehicle type and weight.^{9,10}

12. Various instruments are currently being tested to determine their utility for predicting surface traction for soil trafficability purposes. One instrument (shearograph) used in this study provides a measure of the ultimate cohesion and ultimate angle of internal friction for soil-to-soil and rubber-to-soil shear failures. In this study a normal load of 10 psi was arbitrarily selected as a constant in determining the surface shear strength of a soil. The equipment and procedures used in taking shearograph measurements and in reducing and evaluating the data are described in references 11 and 12.

13. Coarse-grained soils. For coarse-grained soils or clean sands, CI measurements alone are adequate to quantify trafficability. Usually, the strength of clean sands is not altered significantly by changes in moisture content. Clean sands possess adequate strength to support vehicles without critical sinkage. In clean sands the first pass is the most critical, and subsequent passes are made with less difficulty. The 0- to 6-in. layer is considered the critical layer for most military vehicles.

Evaluation of soil trafficability

14. Fine-grained soils and sands with fines, poorly drained. The ability of a given vehicle to complete 40 to 50 passes traveling in a straight-line path over a level area or to execute severe maneuvers in fine-grained soils or sands with fines, poorly drained, is assured if the RCI of the soil in the critical layer in that area is equal to or greater than the vehicle cone index (VCI) assigned to that vehicle. In general, an RCI equal to 50% of the VCI indicates sufficient soil strength to permit one or two straight-line passes of the vehicle.¹³ If the RCI is greater than the VCI of a given vehicle, the additional traction resulting from the excess soil strength can be used to accelerate the vehicle, negotiate slopes, or tow a load.

15. The VCI's for most military vehicles are tabulated in several publications.^{9,10} The referenced publications also contain formulas for computing mobility indexes, means of relating these indexes to VCI's, and the relation of drawbar pull, slope, and force required to tow the vehicle to soil strength.

16. Coarse-grained soils. Studies being conducted on clean sands

have not yet progressed to the point of quantifying trafficability. Results thus far indicate that tracked vehicles usually experience little or no difficulty traversing level, clean-sand areas. The effect of soil strength on vehicle performance (in terms of drawbar pull and slope-climbing ability) of a given tracked vehicle is small; however, a significant difference in performance exists among vehicles having different types of track systems. A wide range in wheeled-vehicle performance occurs as a result of changes in tire pressure, number of tires, and tire size.

Soil Moisture

17. The principal factor influencing the strength of a given soil is its moisture content. Any soil in a comparatively dry state may be trafficable to all military vehicles; but at high moisture content, its strength and consequently its trafficability may be such that only certain vehicles can pass. It is apparent that moisture conditions must be taken into account in any evaluation of the trafficability of soils and, further, that soils must be at similar or equivalent conditions of moisture in order that they can be rated fairly in comparison with each other.

18. Moisture is added to the soil through precipitation, a rising water table, flooding, or irrigation. Moisture is generally depleted from the soil by runoff, gravitational percolation, evaporation, or transpiration through plants. The rate and magnitude of moisture gain or loss and the capacity of the soil to hold water are controlled primarily by the soil and by site characteristics that determine the porosity and permeability of the soil. These characteristics, for the most part, are influenced by the plastic, organic, and textural properties of the soil that are defined in terms of the USCS and the USDA soil classification system.

Climate and season

19. Climate must be considered in any type of soil-moisture analysis. The principal elements of climate consist of precipitation, temperature, atmospheric humidity and pressure, and wind velocity. Of these, precipitation and temperature are the two most important factors controlling the gain and loss of soil moisture. Similar soils within a specific climatic

area will have qualitatively similar seasonal soil-moisture conditions; and conversely, similar soils of different climates will have dissimilar seasonal soil-moisture regimes. Soils in hot, humid climatic areas, for example, generally approach minimum moisture levels more rapidly than soils in cool, humid climatic areas because of higher rates of evapotranspiration.

20. For purposes of this study, a wet season and a dry season are considered, based on the qualitative moisture conditions of the soil. The wet season is defined as the period of the year when generally high soil-moisture contents prevail; it corresponds to the period of maximum precipitation. The dry season is defined as the period of generally low soil-moisture contents, although maximum moisture contents may occur for short periods immediately after several days of heavy rain.

21. Soil-moisture studies conducted at specific sites in various sections of Thailand for continuous periods of almost two years have been used to refine a system for predicting the effects of meteorological factors on the trafficability of soils. The studies show, among other things, that the top 12 in. or so of soil attain relatively high moisture contents during the monsoon season beginning in May or June and continuing through October or November. The distribution of high-rainfall months wherein the rainfall exceeds 100 mm (3.94 in.) a month is recorded in the following tabulation for nine weather stations in Thailand that are located in areas that include most of the study sites.

Location of Weather Station	Years of Record	Percent of Years of Record with Rainfall Exceeding 100 mm (3.94 in.) per Month											
		Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
Chiang Mai	19-1/2	0	0	0	20	80	75	89	100	100	63	11	0

Space and time factors
affecting soil-moisture content

22. In order to estimate the trafficability of a site more accurately, consideration must be given not only to its soil type but also to its topographic position and its general relative moisture-content level. From a study of the data available, certain arbitrary "space" and "time" factors have been designated that are considered essential for optimum accuracy in estimating trafficability on the basis of existing knowledge and available data. Additional data and further study may produce more explicit criteria for estimating the trafficability at a site. However, at the present time, two space factors (low and high topography) and two time factors (wet-season and high-moisture conditions) will be used. These are illustrated in fig. 3 and explained in the following paragraphs.

23. Space factors. The depth to the water table has been found to be a significant factor in determining how wet a site may become. Sites which have a water table within 4 ft of the surface become wetter in the top foot than do sites with the water table below the top 4 ft, even though all other conditions appear to be the same.

a. Low topography. A site of low topography is one at which a water table is known to exist within 4 ft of the surface, perennially or at some time during the year. Such sites usually occur as bottomlands, lower terraces, depressions, or bottoms of slopes, or occasionally as upland flats associated with impervious subsurface layers or pans. They are generally characterized by poor to fair external drainage and moderately poor to very poor internal drainage. If the water table is actually observed at depths of less than 4 ft from the surface at a site at least once, the site automatically qualifies as a low-topography site. If observed data on water-table depth are not available, sites which appear, from observation, likely to have high water tables on the basis of their topographic position, drainage characteristics, proximity to surface water bodies, or soil coloring (gray or blue mottled soils usually indicate the presence of a consistent water table) are judged to be low-topography sites.

b. High topography. Sites of high topography have water tables at depths greater than 4 ft from the surface at all times. These sites are characterized by soils with no impervious layers or pans and with moderate to good internal and external drainage. They are usually located on ridges or upper

Fig. 3. Profile of a typical area showing various topography-moisture conditions during year

slopes. If information on the water table is not available, it is usually possible to determine whether a site is one of high topography through a study of the topographic position and other environmental data available.

24. Time factors. While for this study it would have been desirable to have examined the means and ranges of pertinent soil values measured at a time when the moisture content was at rigorous reference levels, such as field maximum or field capacity, this was not feasible because only a few sites (the prediction-development sites) were known to have been tested when the moisture content was at these levels. In order to realize the benefit of values derived from large masses of data, less rigorous moisture levels, wet-season and high-moisture conditions, were selected. These conditions, or time factors as they are called in this report, are discussed in the following subparagraphs.

- a. Wet-season condition. The wet-season condition is intended to represent the average moisture condition prevailing in soils during the wet season. Data from some of the drier sites were not utilized because the soil was too firm to obtain the necessary data for a determination of rating cone index. Exclusion of these data tended to bias the averages toward wetter-than-average conditions.
- b. High-moisture condition. The high-moisture condition represents the worst trafficability condition that can occur at sites that undergo seasonal changes. Marshes, bogs, swamps, and other perennially wet, soft, spongy areas are prime examples of low-topography areas under a high-moisture condition at all times. Low-lying areas with fluctuating water tables and upland areas with seasonal perched water tables are typical examples of low-topography areas where a high-moisture condition occurs intermittently. Low- and high-topography areas that have been subjected to moderate or heavy rainfall are normally under a high-moisture condition during and immediately following rain periods. In this study a high-moisture condition at high-topography sites could not be identified from the collected data. Consequently, an analysis was not made for this topography-moisture condition and the classification scheme does not include data for this category. Only one set of high-moisture data (cone index, remolding index, rating cone index, sheargraph, and moisture content) was used in the analysis for a given low-topography site. At sites where high-moisture data were collected on more than one day, the set of data selected was for the day of lowest rating cone index. The moisture content for this day was usually, but not

necessarily, the highest recorded at the site. In analyzing the data, a high-moisture condition was considered to have been prevalent at a low-topography site when it was known that the water table was within the top 18 in. of soil. (This 18-in. criterion is based on studies in the United States¹⁴ that show that the strength of a soil decreases at a logarithmic rate with a decrease in depth to the water table and a relatively small rate of change of strength per unit change in depth to the water table when the water table is above a depth of 18 in.)

Slope

25. Vehicles that can traverse certain soils on level surfaces often become immobilized when climbing slopes on similar soils. These immobilizations can be attributed primarily to a downhill force, a function of the vehicle's weight and the angle of slope, which opposes the vehicle's forward thrust. In this report slope is expressed in terms of percent (vertical rise divided by horizontal distance, multiplied by 100).

Slope index

26. The adverse effect of slope on vehicle performance can be expressed by an increase in rating cone index requirements above the vehicle's requirements for level terrain. These excess RCI points, called slope index, may be added to the vehicle cone index and the determination of "go" or "no go" is made by comparing this value with the measured RCI. Detailed procedures are available for determining slope effects and for estimating the maximum slopes negotiable by various vehicle types.^{9,10} Three slope index values, one for tracked vehicles with grousers longer than 1-1/2 in., another for tracked vehicles with grousers shorter than 1-1/2 in., and the third for wheeled vehicles, can be obtained for a given slope from the three respective curves shown in plate 1. If, for example, the slope is 30%, the slope indexes for the three vehicle classes would be 13, 15, and 20, respectively.

Effective rating cone index (ERCI)

27. The ERCI is a combined soil strength-slope value which rates the trafficability of a sloping soil. The index is computed by subtracting the slope index from the rating cone index. For example, if the RCI of a soil

is determined to be 50 and the slope is 30%, the ERCI would be 37 (50 minus 13) for tracked vehicles with grousers longer than 1-1/2 in.; 35 (50 minus 15) for tracked vehicles with grousers shorter than 1-1/2 in.; and 30 (50 minus 20) for wheeled vehicles. The determination of "go" or "no go" on sloping terrain is based on a comparison of the vehicle cone index with the ERCI for the vehicle class. If the VCI is greater than the ERCI, vehicles of this type will not be able to climb the slope; if the VCI is less than the ERCI, the slope is considered negotiable. The ERCI can also be applied and, if desired, mapped in regard to level terrain. In this case, the slope index is zero for all vehicle classes and the ERCI is equal to the RCI of the soil.

PART III: ANALYSIS OF DATA

28. The data were classified and analyzed in terms of both USCS and USDA soil types under a high-topography, wet-season condition, a low-topography, wet-season condition, and a low-topography, high-moisture condition. The following studies were conducted:

- a. A determination of means and standard deviations of cone index, remolding index, rating cone index, moisture content, dry density, and specific gravity for the 6- to 12-in. soil layer; cone index and moisture content for the 0- to 6-in. soil layer; and sheargraph shear strength for surface soils.
- b. A cumulative frequency analysis of rating cone index for the 6- to 12-in. soil layer for each USCS and USDA soil type and for all soils.

Basic Data

29. The data used in these analyses were obtained from 846 sites, 701 of which were located in six MERS study areas, including 103 sites in Chiang Mai, 117 in Khon Kaen, 77 in Nakhon Sawan, 160 in Lop Buri, 182 in Chantheburi, and 62 in Pran Buri. The remainder of the test sites were located in other sections of Thailand. The general locations of the sites are shown in fig. 4. The data were derived from six different test programs conducted for MERS during the period June 1962 through October 1965. The number of sites from each program which provided data for this study and for each analysis is shown in the following tabulation. The procedures

Moisture content, 6-12 in.	61	72	50	40	--	14	237

* Also used in analysis of cumulative frequency.

used in obtaining data in each program are discussed in Appendix A; the data are presented in tables Al-A6.

Method of Computation

30. The General Electric 225 electronic digital computer was employed in computations for this study. Two computer programs were required, one to compute the mean and standard deviation values and one to determine the frequency of occurrence of rating cone index. Data for these programs were supplied to the computer by means of punched IBM cards. These cards form a data retrieval system containing for each site the characteristics of the site (e.g. geographic location, topography class, topographic position, slope, land use, vegetation, etc.), soil data (e.g. percent grain sizes, Atterberg limits, USCS and USDA soil type, specific gravity, organic content, etc.), trafficability data (including CI, RI, RCI, sheargraph measurements, moisture content, and density for wet-season and high-moisture conditions, etc.), and climatological data (e.g. longtime average annual rainfall and temperature, etc.). For a given site, eight IBM cards are required to store approximately 125 pieces of information describing the site, soil, trafficability conditions, and climate.

Mean and Standard Deviation Values of Soil Properties

31. This study establishes the statistical mean and standard deviation values of cone index and moisture content for the 0- to 6- and

6- to 12-in. soil layers; remolding index, rating cone index, dry density, and specific gravity for the 6- to 12-in. soil layer; and sheargraph shear strength for the surface soil. Values for the dynamic soil properties, including moisture content, cone index, remolding index, rating cone index, and sheargraph shear strength, were computed for each of the three topography-moisture condition categories. Values for the static soil properties, including density and specific gravity, were computed only for a wet-season condition (high and low topography, respectively). Data are presented for each of the soil types in the USCS and USDA system in tables 1-7. The mean values in each table, except those for moisture content (table 5), are arranged from top to bottom in decreasing order; the moisture contents are arranged in increasing order. Where data are presented for both the 0- to 6- and 6- to 12-in. layers (tables 1 and 5), the soil types are arranged in order of mean values of the 6- to 12-in. layer. Where data are presented for soil-to-soil shear and soil-to-rubber shear (table 4), the soil types are arranged in order of mean values of soil-to-soil shear.

32. The data were analyzed in terms of mean (\bar{x}) and standard deviation (s) because these are probably the most widely used and most readily understood statistical measures. The mean (commonly termed arithmetic mean or average) is computed by summing the individual measurements and dividing by the total number of measurements. The standard deviation is a measure of the dispersion of the data around the mean. The standard deviation for less than 30 measurements was computed by means of the formula

$$s = \sqrt{\frac{\sum(x - \bar{x})^2}{n - 1}}$$

where

Σ = the sum of

$(x - \bar{x})$ = the deviation of an individual measurement from the mean of all measurements

n = the number of measurements

The -1 was omitted from the denominator of the formula when 30 or more

measurements were used in the computation. When the number of measurements for the specific condition exceeds 30, the interval defined by +1 and -1 standard deviation from the mean will usually contain approximately 68% of the data. Assuming the data are universally valid, if three additional measurements were taken, the values of two would usually fall within this interval. Mean and standard deviation values of a condition with fewer than 30 measurements, and especially of a condition with fewer than 5 measurements, should be viewed with skepticism.

33. The data in table 5 show that mean moisture contents for a given soil type are generally highest under a low-topography, high-moisture condition, intermediate under a low-topography, wet-season condition, and lowest under a high-topography, wet-season condition. If data had been developed for a high-topography, high-moisture condition, the mean moisture content would probably lie between those for the low-topography, wet-season condition, and the low-topography, high-moisture condition. This consistent pattern for all soil types (except a few with mean values that are based on relatively few observations and are therefore questionable) is presumed to be evidence in support of the proper identification of site data into the three arbitrary space-time categories used in this report.

Analysis of strength

34. Cone index. The results of the analysis of CI are given in table 1. The data show mean cone indexes that are generally highest for the USCS coarse-grained soils with fines and USDA gravelly and sandy soils, intermediate for the USCS fine-grained soils and USDA loamy soils, and lowest for the USCS organic soil (OH) and USDA silty and clayey soils. Exceptions are the USCS low-plasticity soils (CL-ML and ML) of the 6- to 12-in. layer which have the highest mean cone indexes of all soils under low-topography, wet-season and high-moisture conditions. (The maximum mean value, for GC, is based on one sample and, therefore, is not reliable.) The data also show higher cone indexes for the 6- to 12-in. soil layer than for the 0- to 6-in. layer; the mean cone indexes for all soils under each of the three topography-wetness conditions range from 57 to 78 units higher in the 6- to 12-in. layer than in the 0- to 6-in. layer.

35. The mean and standard deviation values for each of the soil

types and for all soils of a wetness condition are higher than those reported for temperate climates.¹ This apparent difference can be accounted for by differences in the procedures used in the two studies for measuring cone index. In the temperate-soil study, the capacity of the cone penetrometer was 300 (0.5-in. cone), whereas in this study the capacity of the instrument was extended to 750 (0.2-in. cone) in order to satisfy the needs for soil strength data for other engineering purposes. The average cone index for firm soil is higher when measured with the 0.2-in. cone. For example, the soil tested with the 0.5-in. cone may give several 300+ readings, whereas the same soil tested with the 0.2-in. cone may give readings of 420, 480, etc.

36. Remolding index. The results of the analysis of RI are given in table 2. A comparison of the mean RI's for all soils shows lower average RI's for the low-topography positions. The data show an average RI of 1.03 for soils under high-topography, wet-season condition, an average RI of 0.76 for soils under low-topography, wet-season condition, and an average RI of 0.66 for soils under low-topography, high-moisture condition. Under each topography-moisture condition, the mean remolding indexes are generally highest for the USCS silty, coarse-grained and highly plastic, fine-grained soils and USDA sandy soils, lowest for the USCS low-plasticity, fine-grained soils and USDA loamy soils, and intermediate for the remaining soils. For the moisture levels considered in this report, relatively few soil types have mean RI's greater than 1.0.

37. Rating cone index. The results of the analysis of RCI are given in table 3. Like those for cone index, the data generally show rating cone indexes that are highest for the USCS coarse-grained soils with fines and USDA sandy soils, intermediate for the fine-grained soils, and lowest for the USCS organic soil (OH). The mean RCI for all soils under wet-season condition is about 60 units higher for high-topography than for low-topography position (i.e. 180 versus 121 RCI), and the mean RCI for low-topography position is 35 units higher under the wet-season condition than under the high-moisture condition (i.e. 121 versus 86 RCI). Because of test procedures that provide higher cone indexes in this study, the rating cone indexes are higher and the means and standard deviations are

appreciably greater than those for comparable soils in a temperate climate (see paragraph 35 for an explanation).

38. Sheargraph shear strength. The results of the analysis of sheargraph shear strength of the surface soil for a normal load of 10 psi are given in table 4. The soil types are those for the 0- to 6-in. layer. A comparison of the mean values for a given topography-moisture condition shows little difference between most soil types. The mean shear strengths for soil-to-soil and soil-to-rubber shear appear to be the highest for the high-plasticity and lowest for the low-plasticity USCS soils. A comparison of the mean values for all soils shows a decrease in strength with an increase in the moisture level of the soil for soil-to-soil shear. Only a slight decrease in strength is associated with an increase in moisture level for soil-to-rubber shear. Because the number of samples for most soil types was insufficient for proper statistical analysis, and because the soil type of the 0- to 6-in. layer may, in some cases, be different from that of the surface soil, the results and conclusions drawn from this analysis should be viewed with caution.

Analysis of moisture content

39. The results of the analysis of moisture content are given in table 5. The moisture content is inversely proportional to the soil strength. The data show mean moisture contents to be lowest for the USCS coarse-grained soils with fines and USDA gravelly and sandy soils, intermediate for the USCS low-plasticity, fine-grained soils and USDA loamy soils, and highest for the USCS high-plasticity and organic soils and USDA clayey soils. The mean moisture contents for all soils of the 0- to 6- and 6- to 12-in. layers are about 5% higher for low-topography than for high-topography, wet-season condition and those for low-topography position are about 4% higher for high-moisture than for wet-season condition. Also, mean moisture contents of all soils are about 2% higher for the 0- to 6-in. layer than for the 6- to 12-in. layer.

Analysis of dry density

40. The results of the analysis of dry density are given in table 6. Experience has indicated that changes in dry density of surface soils do not significantly affect their trafficability properties. However, the

density data, along with specific gravity and moisture content data, can be used to estimate the percent saturation of a soil, which is an indicator of the degree of wetness. In this study the density data were analyzed for high- and low-topography, wet-season conditions. The data show densities that are generally highest for the USCS coarse-grained soils with fines and low-plasticity, fine-grained soils and USDA gravelly and sandy soils, intermediate for the USCS moderately plastic, fine-grained soils and USDA loamy soils, and lowest for the USCS highly plastic and organic soils and USDA clayey soils. The mean density for all soils is about 2 lb per cu ft higher under a high-topography condition than under a low-topography, wet-season condition. A comparison of individual USCS soil types shows the density of all soils except CL and SM to be higher for the high-topography position than for the low-topography position. The CL and SM soil densities are slightly less in high positions than they are in low positions.

Analysis of specific gravity

41. The results of the analyses of specific gravity are given in table 7. The specific gravity is a static soil property that does not vary with moisture content; consequently, the data were analyzed only for a wet-season condition. The mean specific gravity for all soils of high topography is 0.04 higher than that for all soils of low topography. Specific gravities are highest for the USCS plastic soils and USDA gravelly and clayey soils, and lowest for the USCS low-plasticity and organic soils and USDA silty and sandy soils.

Cumulative Frequency Analysis of Rating Cone Index

Procedures and presentation of data

42. The data used in this analysis are the same that were used in the mean and standard deviation analyses of RCI under wet-season and high-moisture conditions, respectively. The only difference between this and the previous analysis is in the statistical treatment of the data.

43. RCI's for each soil type under each topography-moisture condition were grouped into intervals of 10 RCI's from 1 to 300 and 300+, i.e. 1 to 10, 11 to 20, 21 to 30...291 to 300, and 300+. The measurements in

each class for the group of 300+ observations were tallied and their percentage of the total number was computed. The percentages were added cumulatively, starting with the percentage of 300+ observations and progressing in order of decreasing RCI. Thus, the 300+ or the larger value of the highest RCI increment for which data were available always was 0% frequency, and the smaller value for the lowest RCI increment for which data were available was 100% frequency. The RCI at 50% frequency is the median value.

44. The data are plotted in cumulative frequency graphs in plates 2-5 for the USCS soil types and in plates 6-9 for the USDA soil types. Graphs for three moisture conditions are usually shown for each soil type. Data were not available for sandy clay (USDA type) and OL and Pt (USCS types), nor were data available for analysis of one or more of the wetness conditions in some of the other soil types. The number of samples (sites) used in each analysis is indicated on its graph.

45. It is noted that where an appreciable number of samples were available for analysis, the three curves drawn for each soil type seldom cross each other. Also, the general range of RCI increases from the high-moisture graph through that for low-topography, wet-season, to the high-topography, wet-season graph. This is taken to be evidence of proper categorization of the basic field data into the three general moisture conditions.

46. Graphs are used to show the manner in which RCI varied. For example, the solid-line curve for CL soils in plate 4 shows that 10% of the CL soils under a low-topography, high-moisture condition had RCI's greater than 127, 20% had values greater than 100, and 30% had values greater than 90, etc.

Estimating probability of vehicle "go"

47. The graphs can be used for estimating the probability of "go" for military vehicles. A soil for which the RCI is greater than the VCI will permit 50 vehicles to pass in straight-line echelon or one vehicle to execute severe maneuvers. Thus, the cumulative frequency corresponding to the VCI indicates the probability of a vehicle's success in a given

soil type under a given general moisture condition. For example, if it is known that the soil type is CL and that the water table is within 18 in. of the surface so that the soil is under a low-topography, high-moisture condition (but specific data on strength cannot be obtained), it can be hypothesized from plate 4 that the M48 tank (VCI = 49) would have a 76% probability of "go."

Analysis for all soils

48. An analysis was made of the cumulative frequency of RCI for all soils under wet-season and high-moisture conditions. The procedures of analysis were the same as those used in the analysis of each soil type (see paragraph 43). The curves developed from the analysis may be used to estimate the percentage of areas trafficable for a given vehicle under a given condition of moisture. A discussion of the curves and their use is presented in paragraph 73.

PART IV: SOIL TRAFFICABILITY CLASSIFICATION
SCHEME AND RELATED STUDIES

49. The soil trafficability classification scheme shown in tables 8 and 9 is essentially a listing of soil types in descending order of their median rating cone indexes under three conditions of moisture: high and low topography under wet-season conditions, and low topography under a high-moisture condition. Information for a high-topography, high-moisture condition was not included in the scheme because data were too few to permit proper analysis. Soil types according to both the USCS and the USDA soil classification system are employed. Thus the scheme can be considered a sixfold scheme for the classification of soils from a trafficability standpoint. The scheme considers the strength of soils in the 6- to 12-in. layer.

50. This part of the report summarizes the vehicle classification categories developed in an earlier study, and describes the soil trafficability classification scheme and its possible application in detail. Tables 10 and 11 supplement the classification scheme by providing specific data on the percent probability of "go" for military vehicles on level and sloping terrain for each of the three general moisture conditions and the two soil classification systems.

Vehicle Categories

51. Different military vehicles require different minimum soil strengths for operation. A soil condition that is easily trafficable for one vehicle may be impassable for another. Therefore, in order to make the soil trafficability classification meaningful, it was necessary to incorporate vehicle requirements into the scheme for estimating the probability of vehicle "go."

52. In an earlier study¹⁵ a system was developed for classifying vehicles on the basis of the minimum soil strength each required for 50 straight-line passes or one severe maneuver on level ground. This system is condensed and repeated here.

<u>Category</u>	<u>VCI Range</u>	<u>Vehicle and Vehicle Types</u>
1	20-29	M29C weasel, M76 otter, Canadian snowmobile, and some lightweight experimental vehicles. Example: VCI of M29C weasel = 25
2	30-49	Engineer and high-speed tractors with comparatively wide tracks and low contact pressures. Examples: VCI of D7 engineer tractor = 40; VCI of M114 armored personnel carrier = 37
3	50-59	Tractors with average contact pressures, tanks with comparatively low contact pressures, and some traileed vehicles with very low contact pressures. Example: VCI of M48 medium tank = 52
4	60-69	Most medium tanks, tractors with high contact pressures, and all-wheel-drive trucks and traileed vehicles with low contact pressures. Example: VCI of M135, 2-1/2-ton truck = 62.
5	70-79	Most all-wheel-drive trucks, a great number of traileed vehicles, and heavy tanks. Example: VCI of 1-1/2-ton, 4x4 dump truck = 73
6	80-99	A great number of all-wheel-drive and rear-wheel-drive trucks, and traileed vehicles intended primarily for highway use. Example: VCI of 1/2-ton, 4x2 pickup truck = 88
7	100 or greater	Rear-wheel-drive vehicles and others that generally are not expected to operate off roads, especially in wet soils. Example: VCI of 5-ton, 4x2 dump truck = 119

The vehicle cone indexes for individual vehicles within the categories are included in Appendix A of reference 15.

Soil Trafficability Classification Scheme, Level Terrain

53. The soil trafficability classification scheme for level terrain is presented in USCS terms in table 8 for high and low topography under wet-season conditions, and for low topography under a high-moisture condition. The scheme is presented in USDA terms in table 9 for the same set of moisture conditions. Information presented in the scheme for each soil type includes a general estimate of the probability of "go" on level terrain for vehicles of various categories. Measurements of soil strength are also included.

Classification of vehicle "go"

54. For the sake of simplicity of presentation, the percent probabilities of vehicle "go" have been arbitrarily classified as follows:

Excellent	greater than 90% probability of "go"
Good	76 to 90% probability of "go"
Fair	50 to 75% probability of "go"
Poor	10 to 49% probability of "go"
No "go"	less than 10% probability of "go"

The probability-of-"go" information is illustrated in tables 8 and 9 by a series of bar graphs, one for each soil type.

Procedures for deriving "go" information

55. The vehicle cone indexes corresponding to 10, 50, 75, and 90% probability of "go," the limiting values of the vehicle "go" groupings, were derived from the cumulative frequency rating cone index graphs (plates 2-9). For example, from the CL soil graph for a low-topography, high-moisture condition (plate 4) it can be seen that the RCI's at 10, 50, 75, and 90% cumulative frequency are 128, 74, 50, and 39, respectively. This means that the soil strength will be greater than 128 RCI 10 times out of 100, greater than 74 RCI 50 times out of 100, greater than 50 RCI 75 times out of 100, and greater than 39 RCI 90 times out of 100. Table 8 shows that vehicles with a VCI greater than 128 will have less than a 10% probability of "go"; those with a VCI ranging from 74 to 128 will have 50% probability of "go"; those with a VCI ranging from 50 to 74 will have a 50 to 75% probability of "go"; those with a VCI ranging from 39 to 50 will have a 76 to 90% probability of "go"; and those with a VCI less than 39 will have greater than 90% probability of "go."

Reliability of "go" information

56. The probability lines delineating the vehicle "go" groupings on the bar graphs in tables 8 and 9 are solid where the data were based on more than four samples and the information shown was considered to be reliable. The lines are broken where less than five samples were used in the analysis or the data were otherwise questionable. The positioning of these

broken lines was based on an assumed RCI estimated from the textural, plasticity, and organic properties of the soil.

57. It should be noted particularly that the occurrence of obstacles was not considered in the probability of "go" estimates for level or sloping terrain. Obstacle components of terrain, such as trees, hedges, dikes, and streams, that present a definite deterrent or obstruction to mobility of vehicles would certainly decrease the probability of "go."

Soil strength information

58. The mean CI, RI, surface sheargraph shear strength for a load of 10 psi, and RCI, and the range of RCI (discussed in Part III) are presented again in tables 8 and 9. It may be noted that the mean RCI for a soil generally is greater than its median RCI, which is the same value as the VCI at 50% probability of "go."

Probability of Vehicle "Go" on Level and Sloping Terrain

59. The percent probabilities of vehicle "go" on level and sloping soils classified in terms of the USCS are presented in table 10 for both high and low topography under wet-season conditions, and for low topography under a high-moisture condition; these data on soils classified in terms of the USDA system are presented in table 11. The data for each soil type-moisture condition include the probabilities of negotiation of level terrain (0% slope) and slopes of 15, 30, and 45% by vehicles in each of the seven vehicle categories. The probabilities were established for the median VCI within vehicle categories 1 through 6 (i.e. 25 VCI for category 1, 40 VCI for category 2, etc.) and for the minimum VCI (100) in category 7, for tracked vehicles with grousers shorter than 1-1/2 in. and for wheeled vehicles. Tracked vehicles with grousers longer than 1-1/2 in. would have a slightly better probability of "go" on sloping soils than that computed for tracked vehicles with shorter grousers. For all practical purposes, however, the difference is insignificant, and the probabilities of "go" listed under the "tracked" column in tables 10 and 11 may be applied to both types of tracked vehicles. The probability of "go" established for a vehicle with a median VCI of a category will closely approximate and may

be used to estimate the probabilities of "go" for other vehicles within the same category.

Procedure for deriving "go" information

60. The probability data were obtained from the cumulative frequency rating cone index graphs presented in plates 2-9. If VCI is substituted for RCI and probability of "go" for cumulative frequency, an estimate of the probability of "go" on level terrain can be made for any vehicle for which a VCI has been computed (discussed in paragraph 47). In order to determine the probability of "go" for a given slope, the slope index, derived from the curve of the vehicle type shown in plate 1, was added to the VCI and the probability of "go" for the soil type-moisture condition was based upon the cumulative frequency reading for this new VCI value. For example, the probabilities of "go" for tracked and wheeled vehicles of 55 VCI (median VCI of category 3) on 0, 15, 30, and 45% slopes of a silt loam soil area under low-topography, wet-season condition were derived as follows. The VCI was substituted for RCI in the abscissa, and the probability of "go" was substituted for cumulative frequency in the ordinate of the silt loam low-topography, wet-season condition graph shown in plate 8. At 55 VCI the probability of "go," read from the graph, was 87%. This value applies to tracked and wheeled vehicles at 0% slope. The slope index at 15% slope, read from the curves of plate 1, was 7 for tracked vehicles with grousers shorter than 1-1/2 in. and 9 for wheeled vehicles. This index was added to the VCI to provide values of 62 (55 plus 7) for the tracked vehicles and 64 (55 plus 9) for the wheeled vehicles. The probabilities of "go" for the VCI values of 62 and 64, read from the graph in plate 8 for silt loam, low topography, and the wet season, were 80 and 79%, respectively. At 30% slope, the slope indexes were 15 and 20, the VCI's became 70 and 75, and the resulting probabilities of "go" were 74 and 68% for the two vehicle types, respectively; at 45% slope, the slope indexes were 27 and 40, the VCI's became 82 and 95, and the probabilities of "go" read from the graph were 60 and 49%, respectively. The probability of "go" can be estimated for any slope and for any vehicle for which a VCI has been computed by using data read from the proper soil type-moisture condition graph and

slope index curve, and following the procedures discussed above.

Reliability of "go" information

61. The probability values for a wet-season condition are undoubtedly influenced by the high-moisture, low-strength bias associated with the basic data (previously discussed in paragraph 24a); thus, the actual probability of "go" would be somewhat higher than that indicated.

62. The number of samples used in the analysis of a particular soil type-moisture condition provides a rough estimate of its reliability. Analyses based on more than 30 samples would generally have a small plus and minus probability error, i.e. the true probability based on an infinite number of the same type of samples would not vary by more than plus or minus a small standard error of estimate. The probabilities of "go," therefore, are considered to be of good reliability. An analysis based on fewer than 30 samples and especially fewer than 15 samples, but more than 4 samples, would have a moderate standard error of estimate (estimated at ± 10 to $\pm 25\%$ probability of "go"). Probabilities based on an analysis of this number of samples are considered to be of only fair reliability and should be viewed with skepticism. Five was arbitrarily chosen as the minimum number of samples needed to provide a reasonably reliable probability value; probabilities of "go" were only estimated for the analyses based on fewer than 5 samples. The estimations were based on assumed strengths estimated from the textural, plasticity, and organic properties of the soil.

Application of Information for Estimating
Trafficability Conditions

63. The information presented in the trafficability classification scheme and probability of "go" tables should be especially useful in military intelligence, military-operations planning, and vehicle-design work. The information may be applied in quantitative or qualitative terms to military problems or to studies of a tactical or strategic nature.

64. The information can be used to estimate trafficability conditions for areas in Southeast Asia that, in most cases, will not be accessible for measurement. Information needed for proper analysis includes

climate and weather, topographic position or water-table conditions, and soil type. Climatological and weather data can be obtained from meteorological records; data on topographic position (and slope if desired) are available from large-scale topographic maps, and information on soil type can be obtained from engineering or pedological reports. It may be reasoned that trafficability-prediction information would not be needed for accessible areas because direct strength measurements with the cone penetrometer could be taken where and when desired. The information, however, could be used in these areas to facilitate a particular study, e.g. the speedy selection of one of several possible access routes, the selection of possible barrier areas (mine fields, etc.) that normally would have good to excellent probabilities of "go," or the selection of broad areas providing the best positions for offensive or defensive operations.

Use of trafficability classification scheme

65. The following paragraphs explain by means of examples how the classification scheme can be used.

66. Season, soil type, and topography. If it is known that the season is the wet season, the soil type is CL, and the topography is low topography, the data in table 8 for low-topography, wet-season condition would be used to determine trafficability. In this case, the probability of "go" on the CL soil would be less than 10% for vehicles with VCI's greater than 185, between 10 and 50% for vehicles with VCI's between 89 and 185, between 50 and 75% for vehicles with VCI's between 58 and 89, between 76 and 90% for vehicles with VCI's between 42 and 58, and greater than 90% for vehicles with VCI's less than 42.

67. Season, soil type, topography, plus rainy weather or high-water-table condition. If, in addition to the knowledge of the season, soil type, and topography, it is known that the soil has been subjected to several days of rain, or if a high water table is known to exist, the low-topography, high-moisture condition data presented in table 8 (or table 9 for USDA soils) would be used. The probability of vehicle "go" on CL soils under these conditions would be less than 10% for vehicles with VCI's greater than 128, between 10 and 50% for vehicles with VCI's between 74 and

128, between 50 and 75% for vehicles with VCI's between 50 and 74, between 76 and 90% for vehicles with VCI's between 39 and 50, and greater than 90% for vehicles with VCI's less than 39.

68. Probability of one straight-line pass for a vehicle. For clayey soils, an RCI equal to about 50% of the VCI usually will permit one straight-line pass of the vehicle.¹³ The probability of a successful operation may be derived from the classification scheme (tables 8 and 9) by projecting a line down from the VCI value multiplied by one-half and reading the probability at its intersection with the particular graph of soil type-wetness condition under consideration. For example, a vehicle with a VCI of 100 would have a recomputed index of 50 (100×0.50). The probability of its making one straight-line pass on a CL soil under low-topography, wet-season condition (from table 8) would be 76 to 90% (estimated at 83%).

Use of probability of "go" tables

69. The following paragraphs explain how the probability tables (tables 10 and 11) can be used. The particular data to be used, like that for the soil trafficability classification scheme, will depend upon the amount and type of information known, i.e. the topography, moisture condition, and the soil type and system in which the soil is classified.

70. Probability of "go" for vehicles within specific VCI categories. The probability of "go" on sloping ground may be estimated for tracked or wheeled vehicles within VCI categories. If, for example, a low-topography, high-moisture condition prevails and the soil is a CL with a 15% slope, the probability of "go" for tracked vehicles in category 3 (VCI 50 to 59) would be 63% (from table 10).

71. Comparison of probabilities between two vehicle categories. The probabilities of "go" can be compared for vehicles in two different categories to estimate the advantage that vehicles in one category would have over vehicles in another. For example, under the same set of conditions as those stated in the preceding paragraph, tracked vehicles in category 5 (VCI 70 to 79) would have a 40% probability of "go" (table 10). Since the table shows the probability of "go" for vehicles in category 3 to be 63%, the difference, 23% (63 minus 40), indicates the advantage in performance of vehicles in category 3.

72. Comparison of probabilities for different soil types and slopes.

The probabilities of "go" for vehicles within a given category can be compared for two or more different soil types and slopes in order to determine quantitatively the advantage that one route would have over another. For example, if tracked vehicles in category 3 were being considered for use in a low-topography area under a high-moisture condition (table 10), the probability of "go" along route A, a CH soil with maximum slopes of 30%, would be 40%; the probability of "go" along route B, a CL soil with maximum slopes of 15%, would be 63%. Thus, from the standpoint of soil type and slope, route B would have a decided advantage of 23% (63 minus 40) over route A.

Estimation of Percentage of Area Trafficable

73. Cumulative frequency curves of the RCI data for all fine-grained soils and coarse-grained soils with fines tested in Thailand are shown for wet-season (high and low topography) and high-moisture (low topography) conditions in plate 10. For purposes of comparison, a similar set of curves is also shown for humid-temperate soils of the United States. The cumulative frequency of RCI, in percent, is plotted for a 10-300 range of RCI. The curves in plate 10 permit one to estimate the percentage of area trafficable for a given vehicle under a wet-season or high-moisture condition. Because the data are biased toward wetter-than-average conditions, estimates of percentages of trafficable areas made from the curves will be smaller than actual, i.e. on the conservative side. Examination of the data reveals that in Thailand a vehicle with a VCI of 80 can make 50 passes in 60% of the soil areas under average conditions in the wet season, and in 40% of the low-lying soil areas under poorest trafficability conditions (high-moisture condition). The same vehicle can make 1 pass (vehicle cone index is 80×0.50 or 40 for 1 pass) in 89% of the area under average conditions in the wet season and in 79% of the low-lying areas under poorest trafficability conditions. It should be emphasized that passable areas are considered strictly in terms of the bearing strength of soils on level surfaces. The presence and orientation of slopes and obstacles and

consideration of the extent of areas of sand would affect the percentage of area trafficable. A comparison of the curves for Thailand and U. S. soils shows that the Thailand soils have slightly higher strengths (68 median RCI for the Thailand soils versus 63 for the U. S. soils) under high-moisture conditions and slightly lower strengths (97 median RCI for the Thailand soils versus 107 for the U. S. soils) under wet-season conditions.

PART V: CONCLUSIONS AND RECOMMENDATIONS

Conclusions

74. Based on the data and discussions presented herein, it is concluded that the scheme for classifying trafficability of Thailand soils has the following advantages:

- a. It rates soil types (both USCS and USDA) according to their median rating cone index under high- and low-topography, wet-season conditions, and under low-topography, high-moisture condition.
- b. From a consideration of cumulative frequency of occurrence of rating cone index, it permits a ready estimate of the chances of successful travel of any military vehicle (whose vehicle cone index is known) on any soil type under three space-time moisture conditions.

75. The conclusions that follow are based on the soil information derived from the various analyses of the basic data.

- a. Soil strength.
 - (1) Soils in low-lying positions (low topography) generally have lower strengths than those in high-lying positions (high topography). (Paragraphs 34-38 and tables 1-4.)
 - (2) The initial strength (cone index) of the 6- to 12-in. soil layer ranges from 57 to 78 units higher than that of the 0- to 6-in. layer. (Paragraph 34 and table 1.)
 - (3) The remolding indexes are generally highest for the silty coarse-grained soils and highly plastic fine-grained soils and lowest for the low-plasticity and loamy fine-grained soils. (Paragraph 36 and table 2.)
 - (4) The remolding index of a soil decreases with an increase in the moisture level. Under highest moisture level (poorest trafficability condition) the soils retain an average of two-thirds of their initial strength after remolding. (Paragraph 36 and table 2.)
 - (5) The initial and remolded strengths of soils (cone index and rating cone index) are highest for the USCS coarse-grained soils with fines and USDA sandy soils, intermediate for the fine-grained soils, and lowest for the organic soils. The rating cone index averages 60 units higher for high-topography than for low-topography position, and that for low-topography positions averages 35 units higher under wet-season condition than under

high-moisture condition. (Paragraphs 34 and 37 and tables 1 and 3.)

- (6) Soils in Thailand have slightly higher strengths under high-moisture condition and slightly lower strengths under wet-season condition than do soils in humid-temperate areas of the United States. (Paragraph 73 and plate 10.)

b. Soil-moisture content.

- (1) For a given topography-moisture level the moisture contents are lowest for the USCS coarse-grained soils with fines and USDA sandy soils, intermediate for the USCS low-plasticity, fine-grained soils and USDA loamy soils, and highest for the USCS high-plasticity and organic soils and USDA clayey soils. (Paragraph 39 and table 5.)
- (2) The average moisture contents in the wet season are about 5% higher for low-topography than for high-topography positions, and those in low-topography positions are about 4% higher under high-moisture than under wet-season conditions. (Paragraph 39 and table 5.)

c. Density.

- (1) The densities are generally highest for the USCS coarse-grained soils with fines and low-plasticity fine-grained soils and USDA gravelly and sandy soils, and lowest for the USCS highly plastic and organic soils and USDA clayey soils. (Paragraph 40 and table 6.)
- (2) The average density is about 2 lb per cu ft higher under high-topography than under low-topography, wet-season condition. (Paragraph 40 and table 6.)

d. Specific gravity.

- (1) Specific gravities are highest for the USCS plastic soils and USDA gravelly and clayey soils, and lowest for the USCS low-plasticity and organic soils and USDA silty and sandy soils. (Paragraph 41 and table 7.)
- (2) The specific gravity of soils on high-topography position averages 0.04 more than that on low-topography position.

e. Probability of "go."

- (1) The probability of "go" for a given vehicle on a given soil type is highest for high-topography, wet-season condition, intermediate for low-topography, wet-season condition, and lowest for low-topography, high-moisture condition. For a given topography-moisture condition, the probability of "go" decreases for soils in the

following order: clean, coarse-grained soils, coarse-grained soils, coarse-grained soils with fines, fine-grained soils, and organic soils. (Table 8.)

- (2) On a basis of soil strength only, vehicles with vehicle cone indexes less than 80 (i.e. practically all military vehicles except those intended primarily for highway use) can negotiate at least 60% of the soil areas during average wet-season conditions and at least 40% of the areas during poorest trafficability conditions. (Paragraph 73 and plate 10.)

Recommendations

76. It is recommended that:

- a. In order to improve the reliability of the probability-of- "go" information that has been derived from a statistical analysis of existing data, new or additional rating cone index information should be collected on USCS soil type-moisture conditions with fewer than 15 observations. This information should include data from all soil types except SM and CL under high-topography, wet-season condition; SP-SM, SM-SC, and organic soil types under low-topography, wet-season condition; and SP-SM, SC, CL-ML, and organic soil types under low-topography, high-moisture condition.
- b. Sheargraph measurements should be incorporated in the trafficability classification scheme if investigations in progress show that these measurements can be related to vehicle traction.

* Probability of "go" based on median vehicle cone index within vehicle categories 1-6 and minimum vehicle cone index for category 7.

Probability of "go" for vehicles in category 7 equal to or less than given value.

t Soils with estimated probabilities.

++ Sample interpretation: A tracked vehicle with a vehicle cone index in the range 50-59 has an 80% probability of "go" on an SiL soil at 15% slope and

APPENDIX A: SOURCES OF DATA AND DETAILED PROCEDURES
USED TO OBTAIN DATA

1. The soil and site data pertinent to the soil trafficability classification analyses are presented in tables Al-A6. These data were obtained in six different programs conducted during the period June 1962 through November 1965 in Thailand. Soil data included are texture, Atterberg limits, USCS and USDA soil type, organic content, and specific gravity. Trafficability data included are moisture content, density, depth to water table, and strength, i.e. cone index (CI), remolding index (RI), rating cone index (RCI), and sheargraph cohesion, adhesion and $\tan \phi$ values, for wet-season and high-moisture conditions. Site data included are geographic locations furnished on Army Map Service map sheets and military grid coordinates, topographic class, topographic position, slope, vegetation, and land use. The general locations of the sites are shown on a map of Thailand in fig. 4 of the main text.

2. In tables Al-A6, the trafficability data for the wet-season condition are the data obtained during one visit to a site or an average of data for two or more visits during the wet season, as noted in the tables. At some sites the RI and, consequently, the RCI could not be determined on some visits because of the firmness of the soil. In determining an average RCI for a site which was visited two or more times, the CI data used were those for which RI measurements were available. Data for high-moisture conditions (water table 18 in. or less from the surface) for all trafficability parameters except sheargraph are usually for one visit. If this condition occurred on more than one visit, the data presented in the tables and used in the analyses were for the day of lowest RCI. Sheargraph data are listed under the high-moisture condition only when the water table was at the surface or free water was above the surface.

3. The following paragraphs are grouped according to the six sources of data and contain a detailed discussion of sampling techniques, number of visits to a site and number of measurements taken during each visit, number and geographical locations of the sites, and other important features of the test programs relevant to the data for each of the sources.

Preliminary Survey Study

4. A preliminary study² was made in Thailand to provide guidance for a planned, long-range research program to develop new methods and apply existing methods for measuring and predicting in quantitative and semiquantitative terms the effects of environmental factors on ground vehicles operating in Southeast Asia. Data were obtained from 202 sites visited during the period June-October 1962 by a team of specialist engineers, physical scientists, and technicians. The test sites were concentrated primarily in four geographic areas: the lower Chao Phraya Delta, the Bangkok Plain, the Khorat Plateau in south-central and eastern Thailand, and the Chiang Mai Basin in northwest Thailand. Also, some of the sites visited were located in the southeastern coastal plain. One visit was made to each site. The data collected for the preliminary survey study from 165 sites that are pertinent to this trafficability classification study are presented in table Al.

Soil and trafficability data

5. At each test site, 10 CI penetrations were made in an area approximately 10 by 20 ft. For each penetration, CI was measured at the surface and at 3-in. vertical increments to a depth of 18 in., and then at 6-in. vertical increments to a depth of 30 in., when possible. When soil conditions permitted testing, RI was measured at each site for the 0- to 6- and 6- to 12-in. layers. In some instances remolding index was measured for the 12- to 18-in. layer. Soil samples were taken for moisture content-density determinations for the same soil layers mentioned above. Representative bulk samples were taken from the 0- to 6- and 6- to 12-in. layers and occasionally from the 12- to 18-in. layer for laboratory tests. Samples were taken in an area approximately 1 ft square.

Site data

6. The site data obtained included geographic location of the test site, topographic position, slope, land use, vegetation, depth of soil, surface-water depth, and depth to water table. An attempt was made to sample a wide range of conditions and soil types with emphasis on testing the lowest and wettest areas on the assumption that the test results would

give some insight into the maximum moisture contents and minimum strengths that various soil types would exhibit during the peak of the wet season.

Trafficability Classification Study

7. Data collected for the trafficability classification study were obtained from 246 sites visited during the period August-October 1964 by a WES soil-trafficability team whose objective was to provide data specifically for the study reported herein. The sites were located within six MERS study areas: Nakhon Sawan, Lop Buri, Chiang Mai, Khon Kaen, Pran Buri, and Chanthaburi. In general, the rainy season extends from May to September in the northern area, from May to October in the central area, and from May to November in the south-central area of Thailand; hence, the period of testing coincided with the expected period of high soil-moisture content during the wettest monsoon season. One visit was made to each site. The data from 238 sites are presented in table A2.

Soil and trafficability data

8. The strength data at each site were obtained as follows. Four sets of CI profiles were taken with measurements taken at the surface and at 3-in. vertical increments to a depth of 18 in.; RI tests were run on two or occasionally three samples from the 6- to 12-in. layer, and surface sheargraph measurements were made at three different locations on the site. Soil samples were taken from the 0- to 6- and 6- to 12-in. layers with the trafficability sampler for determination of moisture content, density, grain-size distribution, Atterberg limits, organic content, and specific gravity. When the soil was too firm for sampling with the trafficability sampler, samples were secured with an Oakfield punch or with a shovel. The locations of test or sampling points for each site are shown in fig. A1.

Site data

9. In each area sites were selected to include a range of different soil types, topographic positions, land uses, and vegetation types with emphasis on the collection of data for soil type-topographic positions for which little or no data had previously been collected, e.g. moderately and highly organic soils on all topographic positions, all soils on upland

- X CONE INDEX**

- △ SHEARGRAPH**

Fig. A1. Site layout

depressions and ridges, and clayey sands, silts, and clays on upland flats. A special effort was made to include an equal number of sites in each combination of soil type and topographic position.

10. Land use at each site was described in one or more of the following terms:

- a. Undisturbed; not obviously used by man or domestic animals.
- b. Disturbed; obviously used by man or domestic animals.
 - (1) Cropland currently in use (excluding hayfields, orchards, vineyards, tree plantations).
Type _____.
 - (2) Cropland currently lying fallow (excluding hayfields, orchards, vineyards, tree plantations). Type _____.
 - (3) Pasture grazed by domestic animals.
 - (4) Hayfields (not currently being grazed).
 - (5) Orchards, vineyards, tree plantations. Type _____.
 - (6) Lawns, recreation areas.
 - (7) Logged, cut for fuel, newly cleared for slash-and-burn agriculture.

11. Since the essence of this program lay in securing a wide range of soil types and topographic position data during the high-moisture period of the wettest monsoon season, no attempt was made to collect detailed vegetation data; instead, the vegetation was described in general but consistent terms that could be readily identified even by relatively untrained observers. These terms are:

- a. Forest. Trees more than 5 m (approximately 16 ft) tall with the crowns of the trees covering more than 90% of the area. Only the trees are significant; smaller plants are ignored.
- b. Woodland. Trees more than 5 m (approximately 16 ft) tall with the crowns of the trees covering between 40 and 90% of the area.
- c. Savanna. Trees more than 5 m (approximately 16 ft) tall with the crowns of the trees covering from 5 to 40% of the area. The "ground cover" may be wild grass, rice, maize, or any mostly herbaceous plants.
- d. Tall scrub forest. Trees from 1.8 (approximately 6 ft) to 5 m (approximately 16 ft) tall with the crowns covering more than 90% of the area.
- e. Tall scrub woodland. Trees from 1.8 (approximately 6 ft) to 5 m (approximately 16 ft) tall with the crowns covering 40 to 90% of the area.
- f. Tall scrub savanna. Trees from 1.8 (approximately 6 ft) to 5 m (approximately 16 ft) tall with crowns covering from 5 to 40% of the area.
- g. Low scrub. Shrubs from 0.7 (approximately 2.3 ft) to 1.8 m (approximately 6 ft) tall with the crowns covering more than 40% of the area.
- h. Low scrub savanna. Shrubs from 0.7 (approximately 2.3 ft) to 1.8 m (approximately 6 ft) tall with the crowns covering from 5 to 40% of the area.
- i. Tall-grass prairie. Herbaceous plants, usually of mostly grasses or grasslike plants, more than 0.7 m (approximately 2.3 ft) high with the plants covering more than 50% of the ground surface.
- j. Short-grass prairie. Herbaceous plants, usually of mostly grasses or grasslike plants, less than 0.7 m (approximately 2.3 ft) high with the plants covering more than 50% of the ground surface.
- k. Barren. More than 50% of the ground surface is bare, i.e. not covered by plants.

In the definitions listed above no distinction is made between cultivated

and noncultivated plants. Thus, a coconut plantation, a rubber grove, or an orchard is usually a "forest" or a "woodland" and a field of mature rice is a "tall-grass prairie."

12. Topographic slope was measured with an Abney hand level at each site on the contiguous area over which no change in true slope occurred. Topographic position was identified as one of the following:

- a. Upland flat (UF)
- b. Upland depression (UD)
- c. Upland ridge (UR)
- d. Upper slope (US)
- e. Lower slope (LS)
- f. Terrace flat (T)
- g. Terrace slope (TS)
- h. Bottomland flat (BF)
- i. Bottomland depression (BD)
- j. Natural levee (NL)
- k. Stream bottom (SB)
- l. Tidal flat (TF)
- m. Drainage ditch (DD)
- n. Beach (B)

Other data collected included depth of water over soil surface, depth to ground water, and depth to bedrock if within several feet of the surface.

Surface Composition Study

13. The objective of the surface composition study³ was to secure data for establishing the range in variation of areal and seasonal soil strength in Thailand and for mapping soils exhibiting similar trafficability characteristics in selected study areas in Thailand. These data were obtained during the period April 1964 through June 1965 by a soil trafficability team. The study areas and the number of visits to sites in each area are shown in the following tabulation.

<u>Area</u>	<u>No. of Visits to Site</u>
Nakhon Sawan	2
Lop Buri	3
Chiang Mai	2
Pran Buri	1
Khon Kaen	2
Chanthaburi	1

The data collected for the surface composition study from 224 sites that are pertinent to the trafficability classification study are presented in table A3.

Soil and trafficability data

14. At each site, soil-strength data were collected for CI, RI, and sheargraph tests. Four or more CI profiles were obtained. Measurements for each profile were made at 1-in. vertical increments to a depth of 18 in. RI tests were conducted on samples from the 0- to 6- and 6- to 12-in. layers. If the results of the tests on two samples from each layer were not in close agreement, a third RI test was made. Sheargraph tests were performed on the soil surface at only one point on the site. Soil samples were taken with the trafficability sampler in 3-in. increments to a depth of 12 in. for the determination of moisture content and density. Bulk samples were taken for laboratory determination of grain-size distribution, Atterberg limits, organic content, and specific gravity. At each site a pit was dug and the soil profile was described to a depth of 18 in. Data also were obtained on the color, pH, and reaction to HCl of soil horizons. From these data the soil series were identified.

Site data

15. The classification of site data for this study was the same as that used in the trafficability classification study (see paragraphs 10-12 of this appendix).

Soil Moisture-Strength Study

16. The objective of the soil moisture-strength study⁴ was to develop means for quantitatively predicting soil-moisture contents and

strength of the soil for use in predicting trafficability of the critical soil layer. Data for this study were obtained from 75 sites during the period May 1964-November 1965 by teams of Thai engineers and technicians. Data were collected during two wet seasons and one dry season. Sites were selected to provide a range in climate, topography, soil type, and land use. The sites were located in seven MERS study areas and in the vicinity of Bangkok, Thailand.

17. Two types of sites, prediction-development (PD) and survey (TS), were established. Data from PD sites were used to develop rainfall-soil moisture-strength relations, and data from the TS sites will be used to check the accuracy of soil moisture-strength predictions that were based on the relations developed from PD site data. Twenty PD and 55 TS sites were established. The PD sites were visited daily to collect unit electrical resistivity data for use in measurement of soil-moisture content, and these sites and the TS sites also were visited one or more times each month to collect trafficability data. The data from this study that are pertinent to the soil trafficability classification study are presented in table A4.

Soil and trafficability data

18. Data from the PD and TS sites were collected in a 21- by 36-ft sampling area divided into 3-ft-square plots. Samples and direct measurements of the soil were taken in three randomly selected plots during each sampling visit to the site.

19. Six CI penetrations, two in each of three randomly selected plots, were made on each visit, and measurements of CI were averaged for the 0- to 6- and 6- to 12-in. layers. RI tests were performed on samples of the 6- to 12-in. layer from each of the three plots. Data from the tests were averaged for each visit. The RCI for a specific visit was then tabulated in the usual manner. An attempt was made to obtain strength measurements concurrently with moisture measurements. CI and especially RI data could not be obtained as frequently as moisture data and at some sites could not be obtained at all during the dry season due to firmness of the soil. At some sites flooding prevented data collection for long periods during the wet season.

20. For each visit sheargraph measurements on the soil surface were made at two spots on each of the three selected plots and averaged. For most sites these data were obtained on four visits during the period of testing.

21. Soil samples of the 3-in. soil layers from the surface to a depth of 18 in. were taken with the trafficability sampler for determination of moisture content. Samples were obtained from two spots in each of three plots. The moisture content data were averaged for each 3-in. layer and for the 0- to 6- and 6- to 12-in. layers.

22. When a thin-walled piston type soil sampler could be used to obtain a relatively undisturbed sample of proper length, that sample was saved for moisture content and density determinations. Also, when the soil was moist, two 2-in. cores were taken with the San Dimas or drive-type sampler for determination of density. The density listed in the summary table for each site is the average of density values determined from tests on piston-type soil samples, or where no such samples were obtained, it is the average of the two density values determined from tests on San Dimas soil samples.

23. The USDA and USCS soil types for each site were determined from mechanical analysis and Atterberg limits of bulk samples taken from the 0- to 6- and 6- to 12-in. layers. The sample tested in the laboratory for each layer was a composite of three samples taken at each end and along a point on one side of the site. The bulk soil samples were also tested to determine the organic content and specific gravity of the soil layer.

Site data

24. Measurements of rainfall, depth to ground water, and ambient temperature were made daily at each of the PD sites.

25. Data describing the topographic position, slope, land use, and vegetation at a site were collected from observations in the field during the period of study. The systems for classifying topographic position, land use, and slope are the same as those used in the trafficability classification study (see paragraphs 10-12 of this appendix).

U. S. Army Cold Regions Research and Engineering
Laboratory (CRREL) Airphoto Pattern Study

26. The purpose of the CRREL airphoto pattern study⁵ was to develop a method for interpreting, classifying, and mapping terrain features of Thailand from airphotos in terms of their effect on ground mobility. Data were obtained from 191 sites during the period 4 September-18 October 1964 by a team of specialist engineers and physical scientists.

27. The sites were located in two MERS study areas selected for detailed study--Lop Buri and Chanthaburi. The sites were selected primarily on the ability of the analyst to recognize tone and texture on aerial photographs. One visit was made to each site. The data from 121 sites pertinent to the trafficability classification study reported herein are presented in table A5.

Soil and trafficability data

28. Three or more CI penetrations were made at each site. For each penetration, CI generally was measured at 1-in. increments from the surface to a depth of 18 in. RI tests were made on samples from the 6- to 12-in. layer. Samples for determination of moisture content and density were taken with the trafficability sampler in 3-in. vertical increments from the surface to a depth of 12 in. The data were averaged for the 0- to 6- and 6- to 12-in. layers. (The density values are questionable and are not listed in the table.) When the soil was too firm to be sampled with the trafficability sampler, samples for moisture only were taken with the Oakfield punch. Bulk samples for determination of grain size, Atterberg limits, organic content, and specific gravity were taken from the 0- to 6- and 6- to 12-in. layers. The soil profile was described briefly in pedological terms.

Site data

29. The topography class, topographic position, and land use identification for each site were based on a general description or were interpreted from aerial or ground photographs of the site.

Terrain-Vehicle Tests

30. The terrain-vehicle test program⁶ was conducted to verify a mathematical model of cross-country vehicle performance previously developed in the United States, by applying it to tropical terrains and modifying it as required. Data for the program were collected in traffic test courses during the period September through October 1965 by a team of engineers, physical scientists, and technicians. The test courses ranged from 10 to 20 ft (hydrologic geometry, designated HG, test courses), to several hundred feet (surface geometry, designated SG, and multiple, designated M, test courses), to several thousand feet (cross-country, designated CC, test courses) in length. For purposes of this study, each of the HG, SG, and M test courses was designated as a site. Each of the CC test courses was subdivided into two or more short stretches, based on changes in soil type, topography, and land use. These stretches were also designated as sites; e.g., test course CC2 was subdivided into sites CC2-A, -B, and -C. The data used in this report are from 23 sites located in the MERS study area of Khon Kaen. Data from the vehicle test program pertinent to the trafficability classification study are presented in table A6.

Soil and trafficability data

31. The data in the table for each site are average values for the total number of visits. On each visit 10 or more CI penetrations were made. For each penetration, CI was measured at the surface, at depths of 1 in. and 3 in., and then at 3-in. vertical increments to 24 or 30 in. Several RI tests were made on samples from the 0- to 6- and 6- to 12-in. layers. Sheargraph measurements of the soil surface were taken in one small area. One set of samples per visit was obtained from the 0- to 1/4- and 0- to 1-in. soil layers for determination of moisture content, and another set of samples was obtained from the 0- to 6- and 6- to 12-in. layers for determination of moisture content and density. Bulk samples for determination of grain size, Atterberg limits, and specific gravity were obtained from the 0- to 6- and 6- to 12-in. layers.

Site data

32. Geographic location, topography class, topographic position, slope, land use, and vegetation data were obtained from general terrain information secured in the field. Again, these data, as tabulated, represent average conditions of the test area.

Table A1 (Continued)

(Continued)

** c_u , ultimate soil-to-soil cohesion; ϕ_u , ultimate soil-to-soil angle of internal friction; a_{ur} , ultimate soil-to-rubber adhesion; α_u , ultimate soil-to-rubber angle of friction.

α_{ur} , ultimate soil-to-rubber angle of friction.

[†] Plus (+) denotes depth of water above surface.

* c_u, ultimate soil-to-soil cohesion; θ_u, ultimate soil-to-soil angle of internal friction; a_{ur}, ultimate soil-to-rubber adhesion; α_{ur}, ultimate soil-to-rubber angle of friction.

DISTRIBUTION LIST FOR ARPA REPORTS

Address	<u>No. of Copies</u>
Secretary of Defense, ATTN: ARPA/AGILE, The Pentagon, Washington, D. C.	4
Commanding General, U. S. Army Materiel Command, ATTN: AMCRD-RV-E, Washington, D. C.	2
Dr. Daniel C. Drucker, Physical Sciences Council, Brown University, Providence, R. I.	1
Dr. Emil H. Jebe, Operations Research Dept., Institute of Science and Technology, University of Michigan, Box 618, Ann Arbor, Mich.	1
Commanding General, U. S. Army Tank-Automotive Center, ATTN: SMOTA-RCL (Mr. R. A. Liston), Warren, Mich.	3
Dr. Ralph E. Fadum, Dean, School of Engineering, North Carolina State College of the University of North Carolina, Raleigh, N. C.	1
Prof. Robert Horonjeff, 3643 Brook St., Lafayette, Calif.	1
Director, Joint Research and Test Activity, APO San Francisco 96243	1
Director, OSD/ARPA R&D Field Unit, APO San Francisco 96243	2
Director, OSD/ARPA R&D Field Unit, APO San Francisco 96346	25
Commander, U. S. Military Assistance Command, APO San Francisco 96346	2
Dr. Clark N. Crain, Director, Project DUTY, Dept. of Geography, University of Denver, Denver, Colo.	2
CINCPAC, Camp H. M. Smith, Oahu, Hawaii	2
Mr. A. C. Orvedal, Chief, World Soil Geography Unit, Soil Conservation Service, USDA, Hyattsville, Md.	2
Commanding General, U. S. Army Natick Laboratories, ATTN: AMXRE-ED (Dr. L. W. Trueblood), Natick, Mass.	2

-------------------------	---

13. ABSTRACT Pertinent soil trafficability data were collected during the wet season at 846 sites in Thailand. The soils were identified according to the Unified Soil Classification System and the U. S. Department of Agriculture textural classification system. Two general topographic positions (high topography and low topography) and two general levels of wetness were considered. A scheme for classifying soils according to their trafficability was developed. The scheme lists the soil types in order of decreasing trafficability under each of three topography-wetness level categories and shows the probability of successful passage on each soil for vehicles of known soil strength requirements. The scheme permits the estimation of the probability of a successful operation for given soil type, topography, and wetness-level conditions. If a choice of several routes and vehicles is available, the determination of the vehicles with the best chances of success over a given route or of the best route for given vehicles can be made.

INSTRUCTIONS						
1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.	10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those imposed by security classification, using standard statements such as:					
2a. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.	(1) "Qualified requesters may obtain copies of this report from DDC."					
2b. GROUP: Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.	(2) "Foreign announcement and dissemination of this report by DDC is not authorized."					
3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.	(3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through ."					
4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.	(4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through ."					
5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.	(5) "All distribution of this report is controlled. Qualified DDC users shall request through ."					
6. REPORT DATE: Enter the date of the report as day, month, year, or month, year. If more than one date appears on the report, use date of publication.	If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.					
7a. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.	11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.					
7b. NUMBER OF REFERENCES: Enter the total number of references cited in the report.	12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring (paying for) the research and development. Include address.					
8a. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.	13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.					
8b, 8c, & 8d. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.	It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U).					
9a. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.	There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.					
9b. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter this number(s).	14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, rules, and weights is optional.
